# 1 Overview

The aim of this document is the description of some hardware solutions useful for developing a product with the [Telit TRIZIUM-GPS module](#).

In this document all the basic functions of a mobile phone will be taken into account; for each one of them a proper hardware solution will be suggested and eventually the wrong solutions and common errors to be avoided will be evidenced. Obviously this document cannot embrace the whole hardware solutions and products that may be designed. The wrong solutions to be avoided shall be considered as mandatory, while the suggested hardware configurations shall not be considered mandatory, instead the information given shall be used as a guide and a starting point for properly developing your product with the [Telit TRIZIUM-GPS module](#). For further hardware details that may not be explained in this document refer to the Telit TRIZIUM-GPS Product Description document where all the hardware information is reported.

Two parts compose the module: a GSM module (TRIZIUM) and a GPS module (GPS 107-04)

These two parts could be used separately or could be connected together in order to use the TRIZIUM module as a controller for the GPS part.

### NOTE

*The information presented in this document is believed to be accurate and reliable. However, no responsibility is assumed by DAI Telecom for its use, nor any infringement of patents or other rights of third parties which may result from its use. No license is granted by implication or otherwise under any patent rights of DAI Telecom other than for circuitry embodied in Telit products. This document is subject to change without notice.*

## 2 Hardware Configurations

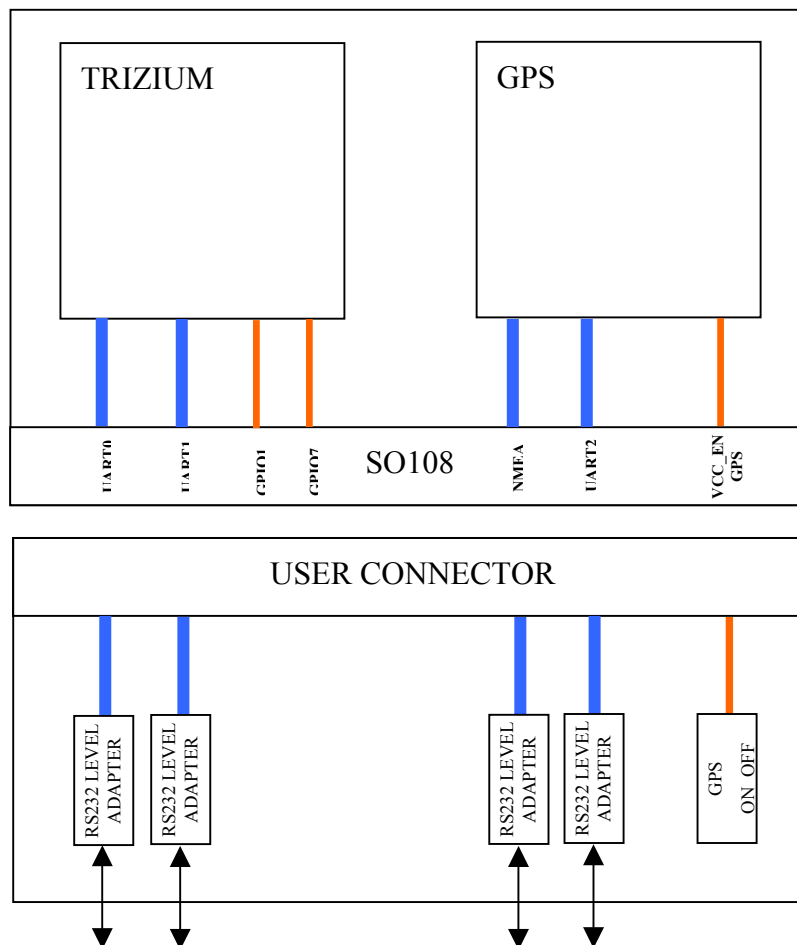

The TRIZIUM-GPS module is configurable to be used in 2 modes:

- Independent Mode
- Internal Mode

### 2.1 Independent Mode

In this case the 2 modules inside the TRIZIUM-GPS (GSM part and GPS part) are not connected together and could be managed separately by the end user in its application.

The two modules have to be switched on/off separately and to be controlled by the external application (refer to the Connector pinout – par.9 for the available signals)

## 2.2 Internal Mode

In this case the 2 modules are connected together through a serial port and the GSM part (TRIZIUM) is acting as a master for the system. The GPIO1 is connected to the VCC\_EN\_GPS and it will be used to switch on / off the GPS module.

## 3 Hardware Commands

### 3.1 Turning ON the TRIZIUM (GSM part)

To turn on the TRIZIUM the pin ONOFF (pin12-SO108) must be tied low for at least 1 second and then released.

The maximum current that can be drained from the ON# pin is 0,1 mA.

A simple circuit to do it is:

**NOTE:** don't use any pull up resistor on the ON# line, it is internally pulled up. Using pull up resistor may bring to latch up problems on the TRIZIUM power regulator and improper power on/off of the module. The line ON# must be connected only in open collector configuration.

**NOTE:** In this document all the lines that are inverted, hence have active low signals are labeled with a name that ends with a "#" or with a bar over the name.

**NOTE:** The TRIZIUM turns fully on also by supplying power to the Charge pin (provided there's a battery on the VBATT pins).

For example:

1- Let's assume you need to drive the ONOFF pin with a totem pole output of a +3/5 V microcontroller (uP\_OUT1):

2- Let's assume you need to drive the ONOFF pin directly with an ON/OFF button:

## 3.2 Turning OFF the TRIZIUM

The turning off of the device can be done in three ways:

- by software command (see TRIZIUM-GPS Software User Guide)
- by hardware shutdown

When the device is shut down by software command or by hardware shutdown, it issues to the network a detach request that informs the network that the device will not be reachable any more.

### 3.2.1 Hardware shutdown

To turn OFF the TRIZIUM the pin ONOFF must be tied low for at least 1 second and then released.

The same circuitry and timing for the power on shall be used.

The device shuts down after the release of the ONOFF pin.

**TIP:** To check if the device has powered off, the hardware line START should be monitored. When START goes low, the device has powered off.

## 3.3 Hardware Unconditional Reboot

To unconditionally Reboot the TRIZIUM the pin RESET# must be tied low for at least 200 milliseconds and then released.

The maximum current that can be drained from the ON# pin is 0,15 mA.

A simple circuit to do it is:

**NOTE:** don't use any pull up resistor on the RESET# line nor any totem pole digital output. Using pull up resistor may bring to latch up problems on the TRIZIUM power regulator and improper functioning of the module. The line RESET# must be connected only in open collector configuration.

**TIP:** The unconditional hardware reboot should be always implemented on the boards and software should use it as an emergency exit procedure.

For example:

- 1- Let's assume you need to drive the RESET# pin with a totem pole output of a +3/5 V microcontroller (uP\_OUT2):

### 3.4 Turning ON/OFF the GPS module

The turning on of the device can be done in three ways:

1) In Independent mode is possible to power on the GPS section using the VCC\_EN\_GPS line on SO108 (pin 61).

In this case the supply voltage is provided to VBAT (pins 1,2,3).

This is an Input line where the Logical Level HIGH switches on the module (a Low level switches it OFF)

The characteristics of the applied signal are described in the table:

Symbol	Parameter	Conditions	Typ	Limit		Units
				min	Max	
IEN	Maximum Input Current at VCC_EN_GPS	VEN = 0.4 and VIN = VBAT	±1			nA
VIL	Maximum Low Level Input Voltage at VCC_EN_GPS	VIN = 2.5 to VBAT		-0.3	0.4	V
VIH	Minimum High Level Input Voltage at VCC_EN_GPS	VIN = 2.5 to VBAT		1.4	VBAT	V

2) In Internal mode is possible to power on/off the GPS section using an AT command for the TRIZIUM (refer to SW user guide). In this case the VCC\_EN\_GPS line is connected externally to the GPIO1 line (pin43)

3) Hardware RESET

To unconditionally turn OFF the GPS part the pin \*RST (pin 69) must be tied low for at least 200 milliseconds and then released.

A simple circuit to do it is:

**NOTE: don't use any pull up resistor on the RST line nor any totem pole digital output. Using pull up resistor may bring to latch up problems on the TRIZIUM power regulator and improper functioning of the module. The line RST must be connected only in open collector configuration.**

## 3.5 Indication of network service availability

By AT commands and LED indication on dedicated output.

The STAT\_LED shows informations on the network service availability and Call status.

In the Trizium family modules the STAT\_LED usually needs an external transistor to drive the STAT\_LED.

Therefore the status indicated in the following table is reversed with respect to the pin status.

STAT\_LED indications

LED status	Device Status
permanently off	device off
fast blinking (period 1s, Ton 0,5s)	Net search / Not registered / turning off
slow blinking (period 3s, Ton 0,3s)	Registered full service
Permanently on	a call is active

## 4 Power Supply

The power supply circuitry and board layout are the most important part in the full product design and they strongly reflect on the product overall performances, hence read carefully the requirements and the guidelines that will follow for a proper design.

### 4.1 Power Supply Requirements

The TRIZIUM-GPS power requirements are:

- *Nominal Supply Voltage:* 3.8 V
- *Max Supply Voltage:* 4.2 V
- *Supply voltage range:* 3.4 V - 4.2 V
- *Max Peak current consumption (impulsive):* 1.9 A
- *Max Average current consumption during GPRS transmission (rms):* 500 mA
- *Max Average current consumption during VOICE/CSD transmission (rms):* 270 mA
- *Average current during Power Saving:*  $\approx 4$  mA
- *Average current during idle (Power Saving disabled)*  $\approx 19$  mA

The GSM system is made in a way that the RF transmission is not continuous, else it is packed into bursts at a base frequency of about 216 Hz, the relative current peaks can be as high as about 2A. Therefore the power supply has to be designed in order to withstand with these current peaks without big voltage drops; this means that both the electrical design and the board layout must be designed for this current flow.

If the layout of the PCB is not well designed a strong noise floor is generated on the ground and the supply; this will reflect on all the audio paths producing an audible annoying noise at 216 Hz; if the voltage drop during the peak current absorption is too much, then the device may even shutdown as a consequence of the supply voltage drop.

---

**TIP:** The electrical design for the Power supply should be made ensuring it will be capable of a peak current output of at least 2 A.

---

## 5 General Design Rules

The principal guidelines for the Power Supply Design embrace three different design steps:

- the electrical design
- the thermal design.
- the PCB layout.

### 5.1 Electrical design Guidelines

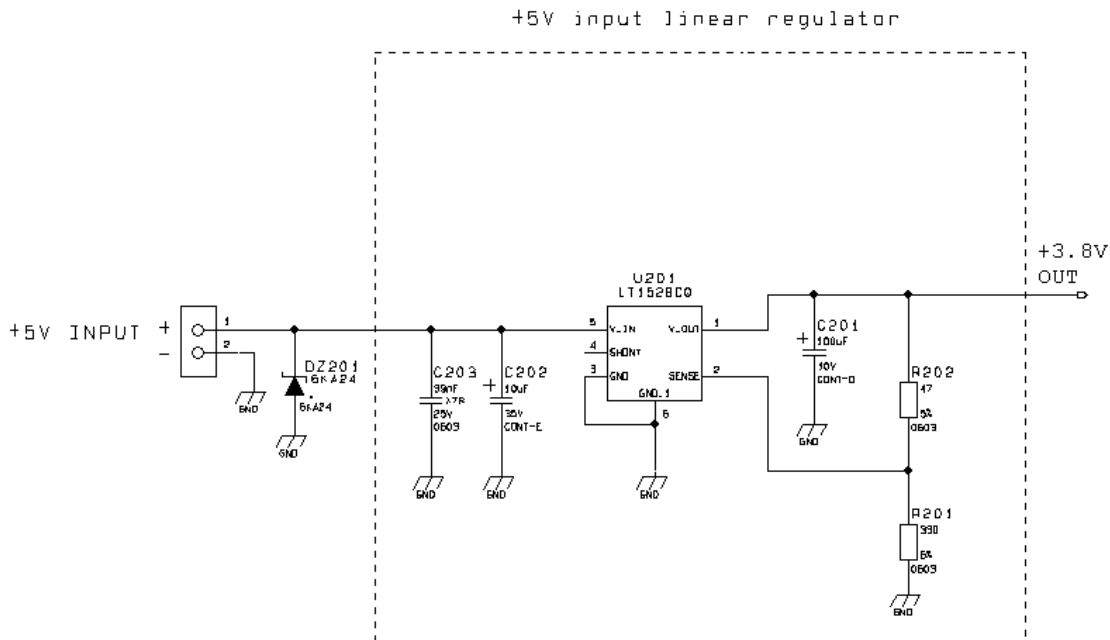

The electrical design of the power supply depends strongly from the power source where this power is drained. We will distinguish them into three categories:

- +5V input (typically PC internal regulator output)
- +12V input (typically automotive)
- Battery

#### 5.1.1 + 5V input Source Power Supply Design Guidelines

- The desired output for the power supply is 3.8V, hence there's not a big difference between the input source and the desired output and a linear regulator can be used. A switching power supply will not be suited because of the low drop out requirements.
- When using a linear regulator, a proper heat sink shall be provided in order to dissipate the power generated.
- A Bypass low ESR capacitor of adequate capacity must be provided in order to cut the current absorption peaks close to the TRIZIUM-GPS, a 100 $\mu$ F tantalum capacitor is usually suited.
- Make sure the low ESR capacitor on the power supply output (usually a tantalum one) is rated at least 10V.
- A protection diode should be inserted close to the power input, in order to save the TRIZIUM-GPS from power polarity inversion.

An example of linear regulator with 5V input is:

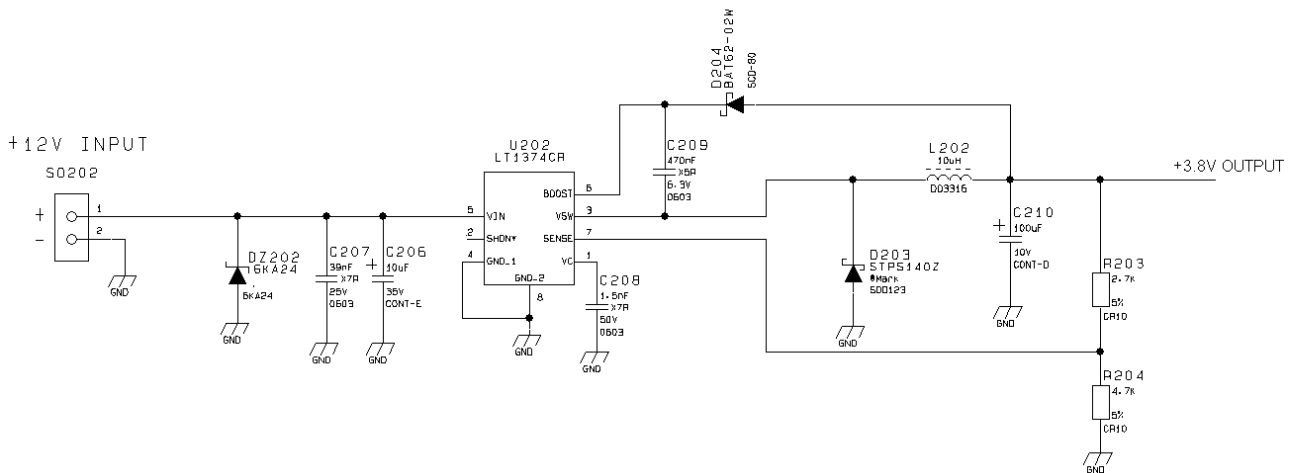

## 5.1.2 + 12V input Source Power Supply Design Guidelines

- The desired output for the power supply is 3.8V, hence due to the big difference between the input source and the desired output, a linear regulator is not suited and shall not be used. A switching power supply will be preferable because of its better efficiency especially with the 2A peak current load represented by the TRIZIUM-GPS.
- When using a switching regulator, a 500Khz or more switching frequency regulator is preferable because of its smaller inductor size and its faster transient response. This allows the regulator to respond quickly to the current peaks absorption.
- For car PB battery the input voltage can rise up to 15,8V and this should be kept in mind when choosing components: all components in the power supply must withstand this voltage.
- A Bypass low ESR capacitor of adequate capacity must be provided in order to cut the current absorption peaks, a 100µF tantalum capacitor is usually suited.
- Make sure the low ESR capacitor on the power supply output (usually a tantalum one) is rated at least 10V.
- For Car applications a spike protection diode should be inserted close to the power input, in order to clean the supply from spikes.
- A protection diode should be inserted close to the power input, in order to save the TRIZIUM-GPS from power polarity inversion. This can be the same diode as for spike protection.

An example of switching regulator with 12V input is:

+12V input switching regulator

### 5.1.3 Battery Source Power Supply Design Guidelines

- The desired nominal output for the power supply is 3.8V and the maximum voltage allowed is 4.2V, hence a single 3.7V Li-Ion cell battery type is suited for supplying the power to the Telit TRIZIUM-GPS module.

The three cells Ni/Cd or Ni/MH 3,6 V Nom. battery types or 4V PB types **MUST NOT BE USED DIRECTLY** since their maximum voltage can rise over the absolute maximum voltage for the TRIZIUM and damage it.

**NOTE: DON'T USE any Ni-Cd, Ni-MH, and Pb battery types directly connected with TRIZIUM. Their use can lead to overvoltage on the TRIZIUM and damage it. USE ONLY Li-Ion battery types.**

- A Bypass low ESR capacitor of adequate capacity must be provided in order to cut the current absorption peaks, a 100µF tantalum capacitor is usually suited.
- Make sure the low ESR capacitor (usually a tantalum one) is rated at least 10V.
- A protection diode should be inserted close to the power input, in order to save the TRIZIUM from power polarity inversion. Otherwise the battery connector should be done in a way to avoid polarity inversions when connecting the battery.

- The battery capacity must be at least 500mAh in order to withstand the current peaks of 2A; the suggested capacity is from 500mAh to 1000mAh.

## 5.1.4 Battery Charge control Circuitry Design Guidelines

The charging process for Li-Ion Batteries can be divided into 4 phases:

- Qualification and trickle charging
- Fast charge 1 - constant current
- Final charge - constant voltage or pulsed charging
- Maintenance charge

The qualification process consists in a battery voltage measure, indicating roughly its charge status. If the battery is deeply discharged, that means its voltage is lower than the trickle charging threshold, then the charge must start slowly possibly with a current limited pre-charging process where the current is kept very low with respect to the fast charge value: the trickle charging.

During the trickle charging the voltage across the battery terminals rises; when it reaches the fast charge threshold level the charging process goes into fast charge phase.

During the fast charge phase the process proceeds with a current limited charging; this current limit depends on the required time for the complete charge and from the battery pack capacity. During this phase the voltage across the battery terminals still raises but at a lower rate.

Once the battery voltage reaches its maximum voltage then the process goes into its third state: Final charging. The voltage measure to change the process status into final charge is very important. It must be ensured that the maximum battery voltage is never exceeded, otherwise the battery may be damaged and even explode. Moreover for the constant voltage final chargers, the constant voltage phase (final charge) must not start before the battery voltage has reached its maximum value, otherwise the battery capacity will be highly reduced.

The final charge can be of two different types: constant voltage or pulsed. TRIZIUM-GPS uses constant voltage.

The constant voltage charge proceeds with a fixed voltage regulator (very accurately set to the maximum battery voltage) and hence the current will decrease while the battery is becoming charged. When the charging current falls below a certain fraction of the fast charge current value, then the battery is considered fully charged, the final charge stops and eventually starts the maintenance.

The pulsed charge process has no voltage regulation, instead the charge continues with pulses. Usually the pulse charge works in the following manner: the charge is stopped for some time, let's say few hundreds of ms, then the battery voltage will be measured and when it drops below its maximum value a fixed time length charging pulse is issued. As the battery approaches its full charge the off time will become longer, hence the duty-cycle of the pulses will decrease. The battery is considered fully charged when the pulse duty-cycle is less than a threshold value, typically 10%, the pulse charge stops and eventually the maintenance starts.

The last phase is not properly a charging phase, since the battery at this point is fully charged and the process may stop after the final charge. The maintenance charge provides an additional charging process to compensate for the charge leak typical of a Li-Ion battery. It is done by issuing pulses with a fixed time length, again few hundreds of ms, and a duty-cycle around 5% or less.

This last phase is not implemented in the TRIZIUM-GPS internal charging algorithm, so that the battery once charged is left discharging down to a certain threshold so that it is cycled from full charge to slight discharge even if the battery charger is always inserted. This guarantees that anyway the remaining charge in the battery is a good percentage and that the battery is not damaged by keeping it always charged (Li-Ion rechargeable battery usually deteriorate when kept fully charged).

Last but not least, in some applications it is highly desired that the charging process restarts when the battery is discharged and its voltage drops below a certain threshold, TRIZIUM-GPS internal charged does it.

As you can see, the charging process is not a trivial task to be done; moreover all these operations should start only if battery temperature is inside a charging range, usually 5°C - 45°C.

The TRIZIUM-GPS measures the temperature of its internal component, in order to satisfy this last requirement, it's not exactly the same as the battery temperature but in common application the two temperature should not differ too much and the charging temperature range should be guaranteed.

---

**NOTE: For all the threshold voltages, inside the TRIZIUM all threshold are fixed in order to maximize Li-Ion battery performances and do not need to be changed.**

---

An example of battery charger application using the internal TRIZIUM-GPS charger can be the:

---

**NOTE: In this application the battery charger input current must be limited to less than 400mA. This can be done by using a current limited wall adapter as the power source.**

---

## 5.1.5 Thermal Design Guidelines

The thermal design for the power supply heat sink should be done with the following specifications:

- *Average current consumption during transmission @PWR level max (rms): 500mA*
- *Average current consumption during transmission @ PWR level min (rms): 100mA*
- *Average current during Power Saving: 4mA*
- *Average current during idle (Power Saving disabled) 19mA*

---

**NOTE:** *The average consumption during transmissions depends on the power level at which the device is requested to transmit by the network. The average current consumption hence varies significantly.*

---

---

**TIP:** *The thermal design for the Power supply should be made keeping a average consumption at the max transmitting level during calls of 500mA rms.*

---

Considering the very low current during idle, especially if Power Saving function is enabled, it is possible to consider from the thermal point of view that the device absorbs current significantly only during calls.

If we assume that the device stays into transmission for short periods of time (let's say few minutes) and then remains for a quite long time in idle (let's say one hour), then the power supply has always the time to cool down between the calls and the heat sink could be smaller than the calculated one for 500mA maximum RMS current, or even could be the simple chip package (no heat sink).

Moreover in the average network conditions the device is requested to transmit at a lower power level than the maximum and hence the current consumption will be less than the 500mA, being usually around 150mA.

For these reasons the thermal design is rarely a concern and the simple ground plane where the power supply chip is placed can be enough to ensure a good thermal condition and avoid overheating.

For the heat generated by the TRIZIUM-GPS, you can consider it to be during transmission 1W max during CSD/VOICE calls and 2W max during class10 GPRS upload.

This generated heat will be mostly conducted to the ground plane under the TRIZIUM-GPS, you must ensure that your application can dissipate it.

### 5.1.6 Power Supply PCB layout Guidelines

As seen on the electrical design guidelines the power supply shall have a low ESR capacitor on the output to cut the current peaks and a protection diode on the input to protect the supply from spikes and polarity inversion. The placement of these components is crucial for the correct working of the circuitry. A misplaced component can be useless or can even decrease the power supply performances.

- The Bypass low ESR capacitor must be placed close to the Telit TRIZIUM-GPS power input pins or in the case the power supply is a switching type it can be placed close to the inductor to cut the ripple provided the PCB trace from the capacitor to the TRIZIUM-GPS is wide enough to ensure a dropless connection even during the 2A current peaks.
- The protection diode must be placed close to the input connector where the power source is drained.

- The PCB traces from the input connector to the power regulator IC must be wide enough to ensure no voltage drops occur when the 2A current peaks are absorbed. Note that this is not made in order to save power loss but especially to avoid the voltage drops on the power line at the current peaks frequency of 216 Hz that will reflect on all the components connected to that supply, introducing the noise floor at the burst base frequency. For this reason while a voltage drop of 300-400 mV may be acceptable from the power loss point of view, the same voltage drop may not be acceptable from the noise point of view. If your application doesn't have audio interface but only uses the data feature of the Telit TRIZIUM-GPS, then this noise is not so disturbing and power supply layout design can be more forgiving.
- The PCB traces to the TRIZIUM-GPS and the Bypass capacitor must be wide enough to ensure no significant voltage drops occur when the 2A current peaks are absorbed. This is for the same reason as previous point. Try to keep this trace as short as possible.
- The PCB traces connecting the Switching output to the inductor and the switching diode must be kept as short as possible by placing the inductor and the diode very close to the power switching IC (only for switching power supply). This is done in order to reduce the radiated field (noise) at the switching frequency (100-500 kHz usually).
- The use of a good common ground plane is suggested.
- The placement of the power supply on the board should be done in such a way to guarantee that the high current return paths in the ground plane are not overlapped to any noise sensitive circuitry as the microphone amplifier/buffer or earphone amplifier.
- The power supply input cables should be kept separate from noise sensitive lines such as microphone/earphone cables.

### 5.1.7 Power supply signal levels (GPS PART)

Signal	Pin n°	Min	Typ	Max	Unit
VGPS	70	3.0	3.3	3.6	V
Ic (standby)				30	μA
Ic (normal)			48	50	mA
VAnt	On GPS RF conn	VGPS-0.5		5.2	V
GS	66	VGPS -0.6		VGPS+0.6	V
AntStat	62	VGPS-0.5		VGPS+0.5	V
GPIO [I]	7..10	VIH = 0.7Vcc		VIL = 0.3Vcc	V
GPIO [O]	7..10	VOH = Vcc-0.8		VOL = 0.4	V
All other pins		-0.3		3.6	V

### 5.1.8 Power supply signal levels (FULL TRIZIUM-GPS)

Signal	Pin n°	Min	Typ	Max	Unit
VBATT	1,2,3	3.40	3.8	4.2	V
Noise level				50	mV rms
VOUT (100 mA max)	14	2.75	2.85	2.95	V

For all the rest of signals refer to the TRIZIUM specification

## 6 Serial Port

The serial port on the Telit TRIZIUM-GPS is the core of the interface between the module and OEM hardware. Several configurations can be designed for the serial port on the OEM hardware, but the most common are:

- RS232 PC com port
- microcontroller UART @ 2.8V - 3V (Universal Asynchronous Receive Transmit)
- microcontroller UART@ 5V or other voltages different from 2.8V

Depending from the type of serial port on the OEM hardware a level translator circuit may be needed to make the system work. The only configuration that doesn't need a level translation is the 2.8V UART.

The serial port on the TRIZIUM is a +2.8V UART with all the 7 RS232 signals. It differs from the PC-RS232 in the signal polarity (RS232 is reversed) and levels. The levels for the TRIZIUM UART are the CMOS levels:

#### Absolute Maximum Ratings -Not Functional

Parameter	Min	Max
Input level on any digital pin when on	-0.3V	+3.75V
Input voltage on analog pins when on	-0.3V	+3.0 V

### Operating Range - Interface levels (2.8V CMOS)

Level	Min	Max
Input high level $V_{IH}$	2.1V	3.3V
Input low level $V_{IL}$	0V	0.5V
Output high level $V_{OH}$	2.2V	3.0V
Output low level $V_{OL}$	0V	0.35V

The signals of the TRIZIUM-GPS serial port are:

#### GSM PART (UART 0):

RS232 Pin Number	Signal	SO108 Pin Number	Name	Usage
1	DCD - dcd_uart	39	Data Carrier Detect	Output from the TRIZIUM that indicates the carrier presence
2	RXD - tx_uart	34	Transmit line *see Note	Output transmit line of TRIZIUM UART0
3	TXD - rx_uart	35	Receive line *see Note	Input receive of the TRIZIUM UART0
4	DTR - dtr_uart	40	Data Terminal Ready	Input to the TRIZIUM that controls the DTE READY condition
5	GND	4-5-6	Ground	ground
6	DSR - dsr_uart	38	Data Set Ready	Output from the TRIZIUM that indicates the module is ready
7	RTS -rts_uart	41	Request to Send	Input to the TRIZIUM that controls the Hardware flow control
8	CTS - cts_uart	36	Clear to Send	Output from the TRIZIUM that controls the Hardware flow control
9	RI - ri_uart	37	Ring Indicator	Output from the TRIZIUM that indicates the incoming call condition

#### GSM PART (UART 1):

Signal	SO108 Pin Number	Name	Usage
RXD - tx_uart	30	Transmit line *see Note	Output transmit line of TRIZIUM UART1 (usable for GPS internal mode)
TXD - rx_uart	31	Receive line *see Note	Input receive of the TRIZIUM UART1 (usable for GPS internal mode)
GND	4-5-6	Ground	ground

### GPS PART (UART0):

Signal	SO108 Pin Number	Name	Usage
RXD - tx_uart	59	Transmit line *see Note	Output transmit line of GPS UART0 (NMEA)
TXD - rx_uart	60	Receive line *see Note	Input receive of the GPS UART0 (NMEA)
GND	4-5-6	Ground	ground

### GPS PART (UART2):

Signal	SO108 Pin Number	Name	Usage
RXD - tx_uart	57	Transmit line *see Note	Output transmit line of GPS UART2 (NMEA, DGPS)
TXD - rx_uart	58	Receive line *see Note	Input receive of the GPS UART2 (NMEA, DGPS)
GND	4-5-6	Ground	ground

 **NOTE:** According to V.24, RX/TX signal names are referred to the application side, therefore on the TRIZIUM side these signal are on the opposite direction: TXD on the application side will be connected to the receive line (here named TXD/ rx\_uart ) of the TRIZIUM serial port and viceversa for RX.

 **TIP:** For a minimum implementation, only the TXD and RXD lines can be connected, the other lines can be left open provided a software flow control is implemented.

## 6.1 RS232 level translation

In order to interface the Telit TRIZIUM-GPS with a PC com port or a RS232 (EIA/TIA-232) application a level translator is required. This level translator must

- invert the electrical signal in both directions
- change the level from 0/3V to +15/-15V

Actually, the RS232 UART 16450, 16550, 16650 & 16750 chipsets accept signals with lower levels on the RS232 side (EIA/TIA-562) , allowing for a lower voltage-multiplying ratio on the level translator. Note that the negative signal voltage must be less than 0V and hence some sort of level translation is always required.

The simplest way to translate the levels and invert the signal is by using a single chip level translator. There are a multitude of them, differing in the number of driver and receiver and in the levels (be sure to get a true RS232 level translator not a RS485 or other standards).

By convention the driver is the level translator from the 0-3V UART level to the RS232 level, while the receiver is the translator from RS232 level to 0-3V UART.

In order to translate the whole set of control lines of the UART you will need:

- 5 driver
- 3 receiver

---

**NOTE:** *The digital input lines working at 2.8VCMOS have an absolute maximum input voltage of 3,75V; therefore the level translator IC shall not be powered by the +3.8V supply of the module. Instead it shall be powered from a +2.8V / +3.0V (dedicated) power supply.*

*This is because in this way the level translator IC outputs on the module side (i.e. TRIZIUM inputs) will work at +3.8V interface levels, stressing the module inputs at its maximum input voltage.*

*This can be acceptable for evaluation purposes, but not on production devices.*

---

An example of level translation circuitry of this kind is:

---

**NOTE:** *In order to be able to do in circuit reprogramming of the TRIZIUM firmware, the serial port on the Telit TRIZIUM-GPS shall be available for translation into RS232 and either it's controlling device shall be placed into tristate, disconnected or as a gateway for the serial data when module reprogramming occurs.*

*Only RXD, TXD, GND and the On/off module turn on pin are required to the reprogramming of the module, the other lines are unused.*

*All applicator shall include in their design such a way of reprogramming the TRIZIUM.*

---

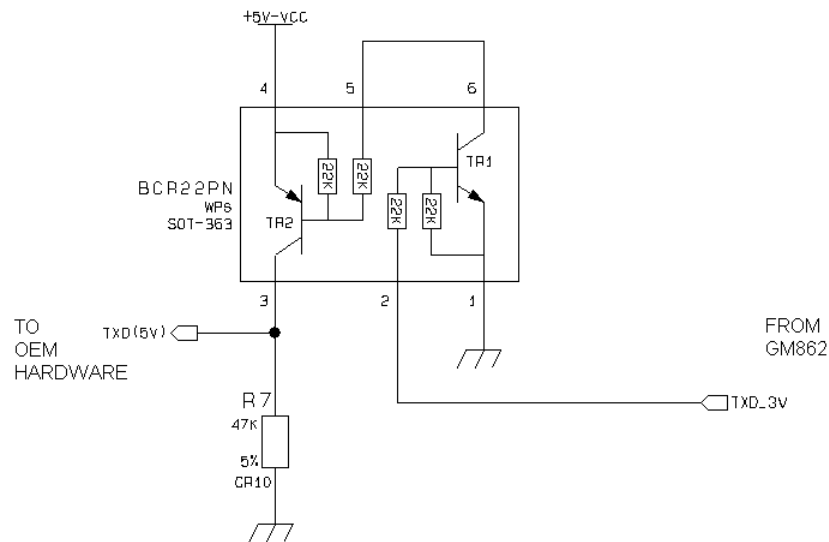

the RS232 serial port lines are usually connected to a DB9 connector with the following layout:

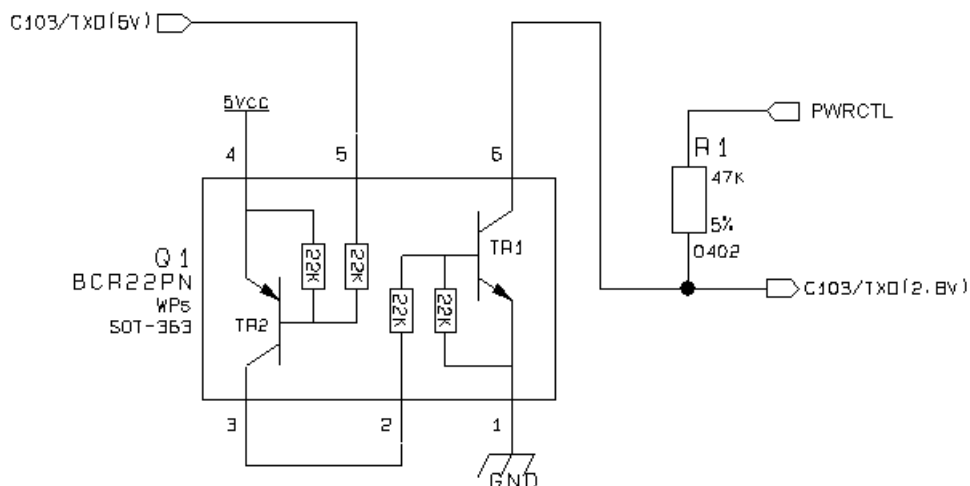

## 6.2 5V UART level translation

If the OEM application uses a microcontroller with a serial port (UART) that works at a voltage different from 2.8 - 3V, then a circuitry has to be provided to adapt the different levels of the two set of signals. As for the RS232 translation there are a multitude of single chip translators, but since the translation requires very few components, then also a discrete design can be suited. For example a possible inexpensive translator circuit for a 5V driver can be:

and for a 5V receiver:

---

***NOTE: The UART input line TXD (rx\_uart) of the TRIZIUM is NOT internally pulled up with a resistor, so there may be the need to place an external 47K $\Omega$  pull-up resistor, either the DTR (dtr\_uart) and RTS (rts\_uart) input lines are not pulled up internally, so an external pull-up resistor of 47K $\Omega$  may be required.***

---

A power source of the internal interface voltage corresponding to the 2.8VCMOS high level is available at the VOUT pin on the connector, whose absolute maximum output current is 100mA.

Pull-up resistors can be connected to the VOUT pin provided that the pulled-up lines are TRIZIUM-GPS input lines connected to open collector outputs in order to avoid latch-up problems on the TRIZIUM-GPS.

Care must be taken to avoid latch-up on the TRIZIUM-GPS and the use of this output line to power electronic devices shall be considered with care, especially for devices that generate spikes and noise such as level translators, digital ICs or microcontrollers, failure in any of these condition can severely compromise the TRIZIUM-GPS functionality.

---

***NOTE: The input lines working at 2.8VCMOS can be pulled-up with 47K $\Omega$  resistors that can be connected directly to the VOUT line.***

***NO disturbing devices should be powered with the VOUT line, otherwise the module functionality may be compromised.***

---

## 7 Microphone

The microphone circuitry is the more noise sensitive and its design and layout must be done with particular care.

### 7.1 Microphone line Characteristic and requirements

The Telit TRIZIUM provides two audio paths for the microphone and the earpiece: the internal and the external audio paths. Only one of the two paths can be active at a time and it is selectable by hardware line AXE or by AT command. The audio characteristics of the two paths are slightly different and this should be kept in mind when designing. The internal audio path should be used for handset function, while the external audio path is suited for hands free function (car kit).

Both microphone paths from the Telit TRIZIUM are balanced and the OEM circuitry should be designed balanced to reduce the common mode noise typically generated on the ground plane, however for particular OEM application needs also an unbalanced circuitry can be used.

The microphone input lines characteristics are:

#### *internal microphone path*

- **line coupling:** AC ( 100nF cond.)
- **line type:** balanced
- **differential input resistance:** 25kOhm
- **line nominal sensitivity:** 50 mV<sub>rms</sub>
- **max input voltage:** 360 mV<sub>rms</sub>
- **microphone nominal sensitivity/analog gain suggested:** -45 dB<sub>V<sub>rms</sub>/Pa</sub> / +24dB
- **echo canceller type:** handset

#### *external microphone path*

- **line coupling:** AC ( 100nF cond.)
- **line type:** balanced
- **differential input resistance:** 25kOhm
- **line nominal sensitivity:** 3 mV<sub>rms</sub>

- **max input voltage:** **22 mV<sub>rms</sub>**
- **microphone nominal sensitivity/analog gain suggested:** **-45 dB<sub>V<sub>rms</sub>/Pa</sub> / +10dB**
- **echo canceller type:** **car kit hands free**

**TIP:** Due to the difference in the echo canceller type, the internal audio path is suited for handset applications while the external audio path is suited for car kit hands free. The headset applications should be made by using the external audio path but **DISABLING** the echo canceller by software AT command. If the echo canceller is left active with the headset, then some echo might be introduced by the echo cancel algorithm.

The nominal sensitivity of the line indicates the voltage level on the TRIZIUM pins that should be present during "normal spoken" conditions: for a handset a voice signal coming from the mouth of the talker at 7 cm of distance from the microphone, producing an acoustic pressure of -4,7 dB<sub>Pa</sub> (@ 1 kHz) on the microphone membrane.

*For example:*

*With the internal mic. having the suggested nominal sensitivity -45dB<sub>V<sub>rms</sub>/Pa</sub> at the "normal spoken" conditions: -4.7dB<sub>Pa</sub> on the microphone membrane.*

*At that acoustic pressure the voltage output from the microphone is:*

$$\text{Voltage Output (dB)} = (-45) + (-4.7) = -49.7 \text{ dB}_{V_{rms}}$$

*corresponding to:*

$$\text{Voltage Output} = 10^{(-49.7/20)} = 3.3 * 10^{-3} V_{rms}$$

*by having the microphone gain set to +24 dB (corresponding to 15.8 times) the signal in the nominal conditions on the input mic. pins of the TRIZIUM will be:*

$$\text{Voltage @ TRIZIUM\_mic} = 3.3 * 10^{-3} * 15.8 = 51 \text{ mV}_{rms}$$

During the spoken conditions the signal varies according to the volume of the voice of the talker, usually a rough thumb rule for the dynamic range may be considered:

- \* +20dB (10 times) at maximum voice level (talker screaming)
- \* -50 dB (1/300 times) at minimum voice level (talker whispering).

For the handsfree/car kit microphone the voice attenuation due to the distance between the microphone and the talker must be taken into account when designing the microphone amplifier.

For a car cabin usually the distance between the talker and the mic. is about 50cm; in these conditions the attenuation can be considered as a thumb rule around 20dB.

Another thing to consider, especially for cabin car use, is the fact that the external mic. will pick up also ambient noise; to overcome this problem it is preferable to set the gain of the microphone 10dB lower with respect to the calculated value for a nominal sensitivity. The corresponding reduction in signal level will be compensated by an increased voice volume of the talker which will speak louder because of the ambient noise.

For the headset we shall distinguish two different types: the headsets having the microphone sustained close to the mouth and the headsets having the microphone on the earpiece cable.

The same considerations for the additional voice attenuation due to the distance from the microphone and the noise pick up can be made for the headset having the microphone on the earpiece cable, while the other kind of headset shall be threaten as an handset.

*For example:*

*With the external mic. having the suggested nominal sensitivity  $-45dB_{V_{rms}/Pa}$*

*at the "normal spoken" conditions:  $-4.7dB_{Pa}$  at 7 cm from the mouth of the talker and with a further attenuation of 20dB due to the distance from the microphone (about 50 cm).*

*At that acoustic pressure the voltage output from the microphone is:*

$$\text{Voltage Output (dB)} = (-45) + (-4.7) - 20 = -69.7 \text{ dB}_{V_{rms}}$$

*corresponding to:*

$$\text{Voltage Output} = 10^{(-69.7/20)} = 3.3 * 10^{-4} V_{rms}$$

*by having the microphone gain set to +10 dB (corresponding to 3 times) the signal in the nominal conditions on the input external mic. pins of the TRIZIUM will be:*

$$\text{Voltage @ TRIZIUM\_extmic} = 3.3 * 10^{-4} * 3 = 1 \text{ mV}_{rms}$$

*Hence in these conditions the signal level on the input pins of the external mic. of the TRIZIUM is 10 dB (3 times) lower than the nominal, as suggested.*

The microphones usually need a biasing network that provides the necessary DC current to the mic., this will be explained further on.

In the EVK all the microphone input jacks have the hot wire connected to the central pole.

## 7.2 General Design Rules

There are several configurations for the audio path, but the most effective difference is between balanced and unbalanced microphone.

It is highly recommended to keep the whole microphone path balanced even if this means having 2 wires connecting the microphone instead of one needed (plus ground) in the unbalanced case. The balanced circuitry is more suited because of its good common mode noise rejection, reducing the 216 Hz burst noise produced during the GSM transmissions.

- Where possible use balanced microphone circuitry
- Keep the microphone traces on the PCB and wires as short as possible.
- If your application requires an unbalanced microphone, then keep the lines on the PCB balanced and "unbalance" the path close to the microphone wire connector if possible.
- For the microphone biasing voltage use a dedicated voltage regulator and a capacitor multiply circuit.
- Make sure that the microphone traces in the PCB don't cross or run parallel to noisy traces (especially the power line)
- If possible put all around to the microphone lines a ground trace connected to the ground plane by several vias. This is done in order to simulate a shielded trace on the PCB.
- The biasing circuit and eventually the buffer can be designed in the same manner for the internal and external microphones.

## 7.3 Microphone Biasing

The electret microphones usually need a biasing voltage to work properly. Refer to your microphone provider for the characteristics required.

---

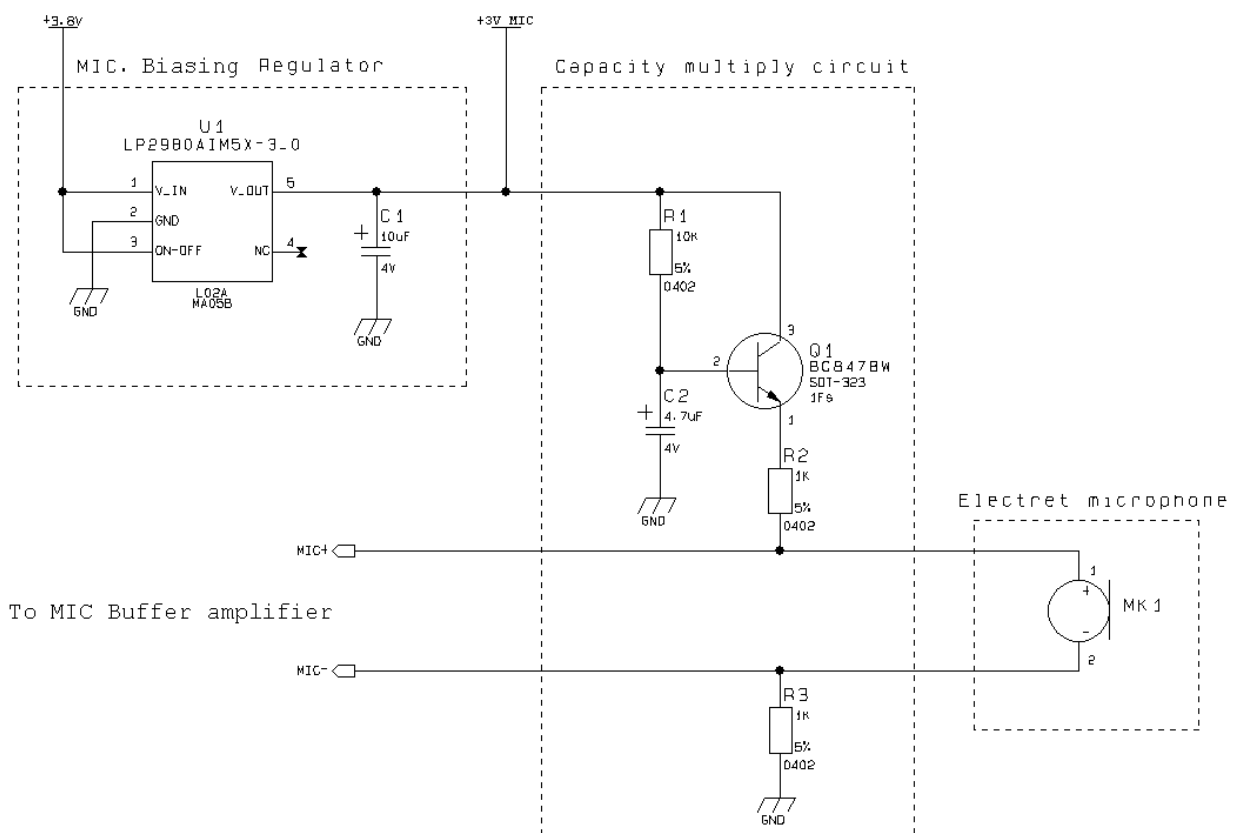

***NOTE: The microphones have a hot wire were the positive biasing must be connected, usually it is indicated by a + sign or a red point. If the polarity of the bias is reversed, then the microphone will not work properly. For this reason be sure to respect the mic. biasing polarity.***

---

## 7.3.1 Balanced Microphone biasing

The balanced microphone bias voltage should be obtained from a dedicated voltage regulator, in order to eliminate the noise present on the power lines. This regulator can be the same for all the audio paths. The microphone should be supplied from a capacitor multiply circuit.

For example a circuit for the balanced microphone biasing can be:

**NOTE:** In the balanced application the resistors R2 and R3 must have the same value to keep the circuit balanced.

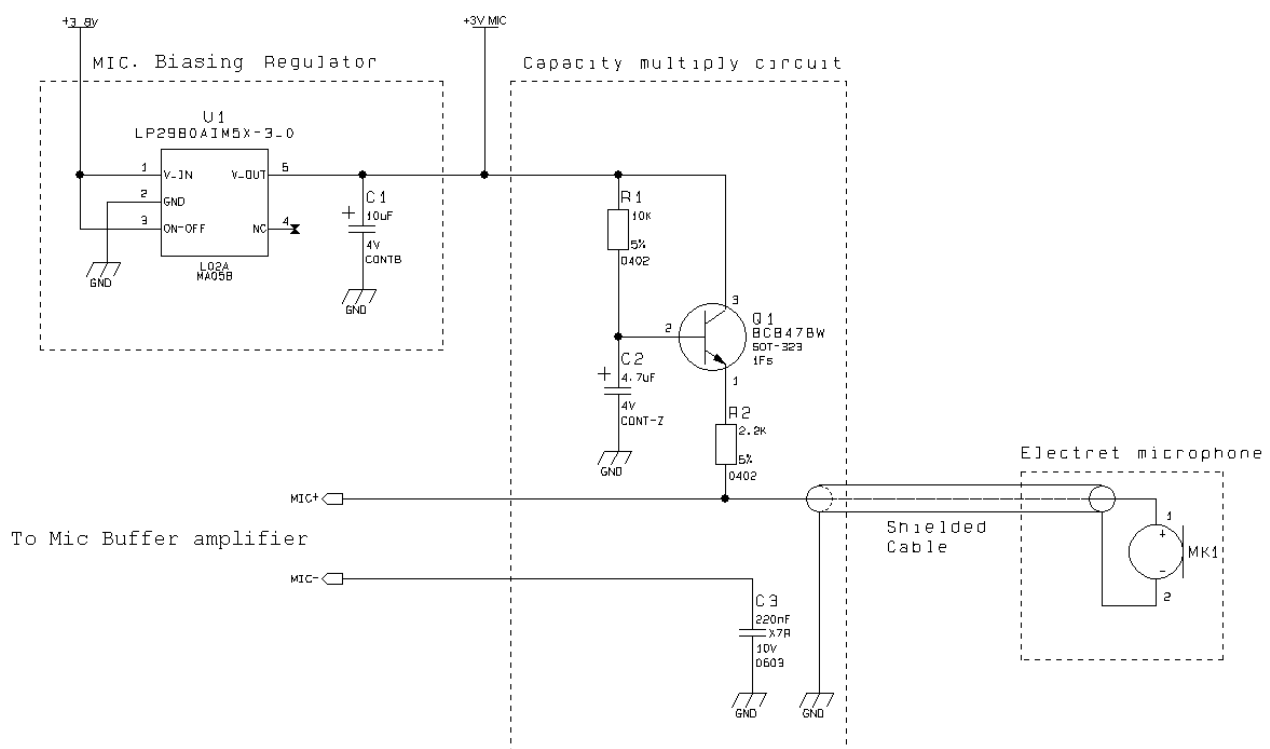

**NOTE:** The cable to the microphone should not be shielded, instead a twisted pair cable shall be used.

**NOTE:** The microphone sensitivity changes with the value of R2 and R3. Usually the microphones are characterized with 2kOhm biasing resistance, so try to keep the sum of R2 and R3 around 2kOhm. Refer to your microphone manufacturer for the mic. characteristics.

## 7.3.2 Unbalanced Microphone biasing

The unbalanced microphone biasing voltage should be obtained from a dedicated voltage regulator, in order to eliminate the noise present on the power lines. This regulator can be the same for all the audio paths. The microphone should be supplied from a capacitor multiply circuit.

For example a circuit for the unbalanced microphone biasing can be:

**NOTE:** In the unbalanced application the capacitor C3 shall be > 200nF otherwise the frequency response will be cut at low band frequencies (down to 300Hz). This capacitor can be placed close to the MIC- pin (EXT\_MIC- or INT\_MIC- depending on the audio path chosen) or if possible it should be placed close to the shielded cable connector. If the ground return path is well designed, then it is possible to eliminate the C3 capacitor, provided the buffer is close to the mic. input.

**NOTE:** The cable to the microphone should be shielded.

**NOTE:** The microphone sensitivity changes with the value of R2. Usually the microphones are characterized with 2kOhm biasing resistance, so try to keep the value of R2 around 2kOhm. For mic. characteristics refer to the manufacturer.

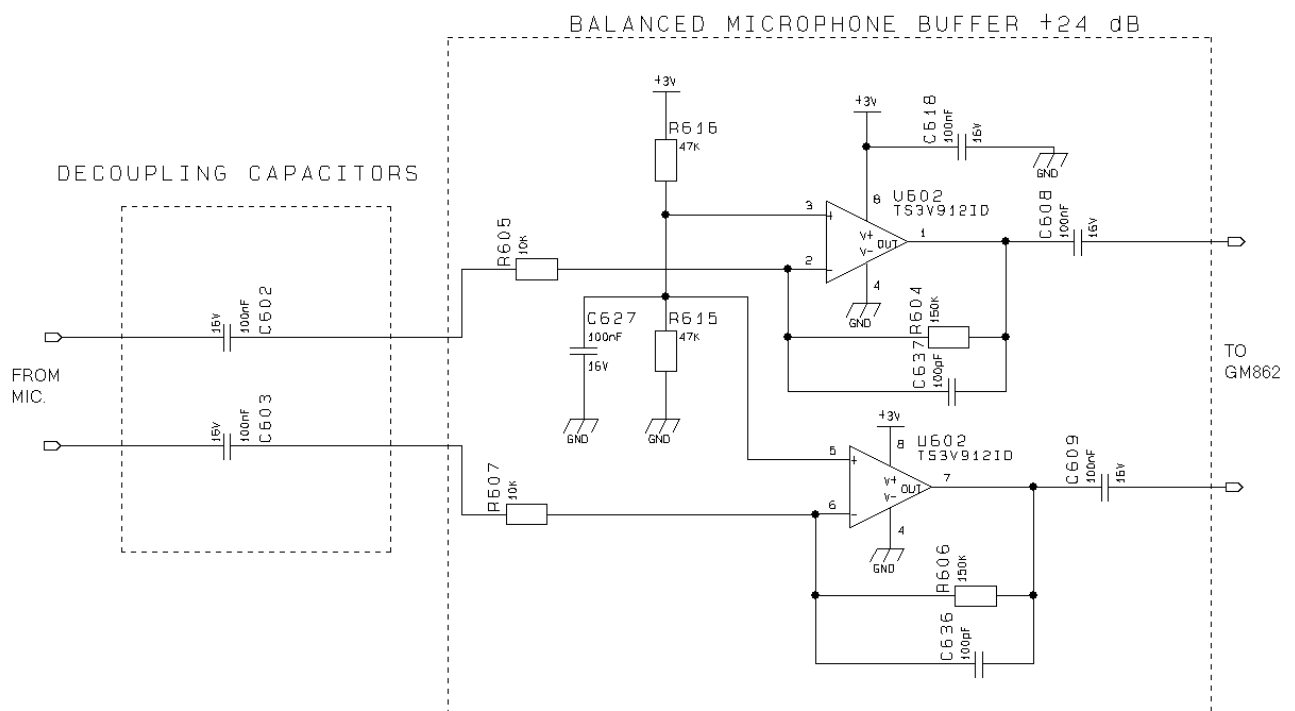

## 7.4 Microphone buffering

As seen previously, a microphone shall be connected to the input pins of the TRIZIUM through a buffer amplifier that boosts the signal level to the required value.

Again the buffered microphone circuitry can be balanced or unbalanced. Where possible it is always preferable a balanced mic. solution. The buffering circuit shall be placed close to the microphone or close to the microphone wire connector.

### 7.4.1 Buffered Balanced Mic.

A sample circuit can be:

This circuit has a gain of 15 times (+24 dB), and is therefore suited for the internal mic. input, having a microphone with a sensitivity close to the suggested one (-45 dB<sub>Vrms/Pa</sub>), if the used microphone has a different sensitivity, or if the buffer is connected to the external mic. input, then a gain adjustment shall be done by changing resistors R604-R605 and R606-R607 and as a consequence the capacitors C636 and C637 to maintain the bandwidth 150-8000 (-3dB).

The buffer gain is given by the formula:

$$Gain = \frac{R604}{R605} = \frac{R606}{R607}$$

The C636 and C637 capacitors are placed in order to cut off the gain at higher frequencies than the transmitted GSM band, the cutoff frequency (-3dB) should be 8 kHz in order to have -1dB at 4Khz. The cutoff frequency is given by the formula:

$$freq. = \frac{1}{2\pi * R604 * C637} = \frac{1}{2\pi * R606 * C636} \text{ [Hz]}$$

*For example:*

*- Let's assume you have a microphone with these characteristics:*

*- sensitivity -45 dB<sub>Vrms/Pa</sub>*

*and you want to use it in the internal mic. audio path.*

*With the mic. having nominal sensitivity -45dB<sub>Vrms/Pa</sub> at the "normal spoken" conditions: -4.7dB<sub>Pa</sub> at 7 cm from the mouth of the talker.*

*At that acoustic pressure the voltage output from the microphone is:*

$$\text{Mic Voltage Output (dB)} = (-45) + (-4.7) = -49.7 \text{ dB}_{Vrms}$$

*corresponding to:*

$$\text{Mic\_Voltage\_Output} = 10^{(-49.7/20)} = 3.3 * 10^{-3} \text{ V}_{rms}$$

*in order to have a signal of 50 mV<sub>rms</sub> on the TRIZIUM internal mic. inputs then the buffer must have a gain of:*

$$\text{Voltage @ TRIZIUM\_intmic / Mic\_Voltage\_Output} = (50 * 10^{-3}) / (3.3 * 10^{-3}) = 15$$

*Hence in these conditions the signal level on the input pins of the internal mic. of the TRIZIUM is 24 dB (15 times) higher than the microphone output and therefore the buffer has to gain 24 dB.*

*The corresponding values for the resistors on the buffer could be ( if we keep the input resistance 10kOhm )*

$$R604 = R606 = gain * R603 = gain * R605 = 15 * 10 = 150 \text{ kOhm}$$

*The commercial values of 150kOhm & 10kOhm are then chosen.*

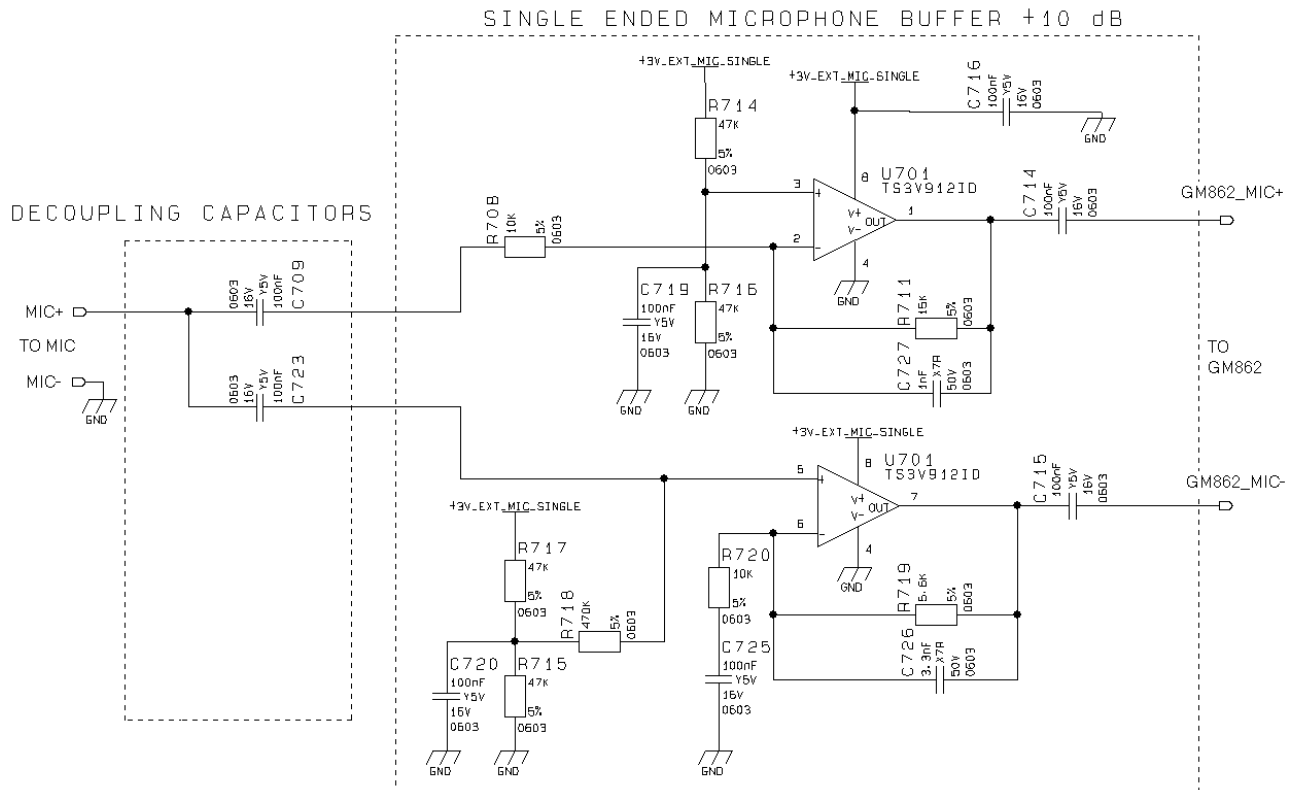

*As a consequence the values of the capacitors C636 and C637 shall be:*

$$C636 = C637 = 1 / (2\pi * 8000 * R606) = 132 * 10^{-12} \text{ F}$$

*A commercial value of 100pF is then chosen.*

## 7.4.2 Buffered Unbalanced (Single Ended) Mic.

A sample schematic for a buffered unbalanced (single ended) microphone can be:

The schematic does not include the required mic. biasing circuitry. For the biasing the same circuit as seen before can be used; to be noticed that the capacitor C3 on the unbalanced biasing circuit is not anymore needed if this Buffered design is used.

Two different configurations are used, one inverting and the other not inverting, hence an additional +6dB (2 times) gain is achieved by doubling the mic. signal path.

The gain of the not inverting buffer is given by the formula:

$$Gain = 1 + \frac{R719}{R720}$$

and hence it cannot be less than 1. In the example shown the gain of the not inverting buffer is 1,5 (4dB).

While the gain of the inverting buffer is given by the formula:

$$Gain = \frac{R711}{R708}$$

As shown in the balanced buffered mic. the gain adjustments can be done by changing R719 - R720 and R708 - R711 and as a consequence the capacitors C726 and C727.

The bandwidth (-3dB) is given by the approximated formula (considering  $C725 \gg C726$ ) :

$$freq. = \frac{1}{2\pi * R719 * C726} = \frac{1}{2\pi * R711 * C727} \text{ [Hz]}$$

The buffer bandwidth at -3dB shall be 8kHz.

Note that the biasing of the operational amplifier is given for the inverting amplifier by the series divider R714-R715. The 100nF capacitor C719 is needed to filter the noise that could be coupled to that divider. For the not inverting operational the biasing is given by a different divider R715-R717 with the capacitor C720 and through a series resistor R718 of 470KOhm.

*For example:*

*- Let's assume you have a microphone with these characteristics:*

*- sensitivity -45 dB<sub>Vrms/Pa</sub>*

*and you want to use it in the external mic. audio path.*

*With the mic. having nominal sensitivity -45dB<sub>Vrms/Pa</sub> at the "normal spoken" conditions: -4.7dB<sub>Pa</sub> but at 50 cm from the mouth of the talker an additional 20 dB loss shall be considered.*

*At that acoustic pressure the voltage output from the microphone is:*

$$\text{Mic Voltage Output (dB)} = (-45) + (-4.7) - 20 = -69.7 \text{ dB}_{Vrms}$$

*corresponding to:*

$$\text{Mic\_Voltage\_Output} = 10^{(-69.7/20)} = 3.3 * 10^{-4} V_{rms}$$

*in order to have a signal of 1 mV<sub>rms</sub> (10 dB lower than the nominal input for the TRIZIUM external mic. path) on the TRIZIUM internal mic. inputs then the buffer must have a gain of:*

$$\text{Voltage @ TRIZIUM\_intmic/ Mic\_Voltage\_Output} = (1 * 10^{-3}) / (3.3 * 10^{-4}) = 3$$

*Hence in these conditions the signal level on the input pins of the internal mic. of the TRIZIUM is 10 dB (3 times) higher than the microphone output and therefore the buffer has to gain 10 dB.*

*To calculate the resistor values it must be kept in mind that balancing the line will double the signal and hence already add +6 dB, therefore the buffer must gain only 1.5 times.*

*The corresponding values for the resistors on the buffer could be ( if we keep the input resistance 10kOhm )*

$$R711 = gain * R708 = 1.5 * 10 = 15 \text{ kOhm}$$

$$R719 = (\text{gain} - 1) * R720 = (1.5 - 1) * 10 = 5 \text{ kOhm}$$

The commercial values of 15kOhm & 5.6kOhm are then chosen.

As a consequence the values of the capacitors C726 and C727 shall be:

$$C726 = 1 / (2\pi * 8000 * R719) = 3.5 * 10^{-9} \text{ F}$$

$$C727 = 1 / (2\pi * 8000 * R711) = 1,2 * 10^{-9} \text{ F}$$

The commercial values of 3.3nF and 1nF are then chosen.

## 8 Speaker

### 8.1 Speaker lines characteristics and requirements

The Telit TRIZIUM provides two audio paths for both the microphone and the earpiece: the internal and the external audio paths. Only one of the two paths can be active at a time and it is selectable by hardware line AXE or by AT command. The audio characteristics of the two paths are slightly different and this should be kept in mind when designing your application. The internal audio path should be used for handset function, while the external audio path is suited for hands free function (car kit).

Both speaker outputs from the Telit TRIZIUM are bridged type and the OEM circuitry shall be designed bridged to reduce the common mode noise typically generated on the ground plane and to get the maximum power output from the device; however for particular OEM application needs also a single ended circuitry can be designed.

The TRIZIUM speaker output lines characteristics are:

*internal speaker path ( EAR\_MT+, EAR\_MT- )*

- |  |   |
|--|---|
| • <b>line coupling:</b>                            | <b>DC</b>   |
| • <b>line type:</b>                                | <b>bridged</b>  |
| • <b>speaker impedance (operating conditions):</b> | <b><math>\geq 16 \text{ Ohm} \pm 5\% @ 1\text{kHz}</math></b> |
| • <b>minimum load impedance:</b>                   | <b>15 Ohm</b>   |
| • <b>signal bandwidth:</b>                         | <b>150 - 8000 Hz @ -3 dB</b>                                  |
| • <b>maximum differential output:</b>              | <b>850 mV<sub>rms</sub></b>                                   |
| • <b>rated output power:</b>                       | <b>10 mW</b>  |

- **maximum power output:** **30 mW**
- **volume level steps (SW):** **- 2 dB**
- **number of volume steps(SW):** **10**

*external speaker path ( EAR\_HF+ , EAR\_HF- )*

- **line coupling:** **DC**
- **line type:** **bridged**
- **speaker impedance (operating conditions):**  **$\geq 16 \text{ Ohm} \pm 15\% @ 1\text{kHz}$**
- **minimum load impedance:** **15 Ohm**
- **signal bandwidth:** **150 - 8000 Hz @ -3 dB**
- **maximum differential output:** **425 mV<sub>rms</sub>**
- **rated output power:** **2.5 mW**
- **maximum power output:** **7.5 mW**
- **volume level steps (SW):** **- 2 dB**
- **number of volume steps (SW):** **10**

## 8.2 General Design rules

There are several configurations for the audio output path, but the various design requirements can be grouped into three different categories:

- handset earphone (low power, typically a handset)
- hands free earphone (low power, typically a headset)
- car kit speakerphone (high power, typically a speaker)

The three groups have different power requirements, usually the first two applications need only few mW of power, which can be directly drained from the TRIZIUM-GPS pins, provided a suited speaker is used. This direct connect design is the cheaper and simpler solution and will be suited for the most of the earphone design requirements. There's no need to decouple the output ear lines if a suited earpiece is connected. For the last group, the speakerphone, a power amplifier is required to raise the output power up to 5-10W required in a car cabin application.

All the designs shall comply with the following guidelines:

- Where possible use a bridged earphone circuitry, to achieve the maximum power output from the device.
- Keep the earphone traces on the PCB and wires as short as possible.
- If your application requires a single ended earpiece and you want a direct connection, then leave one of the two output lines open and use only the other referred to ground. Remember that in this case the power output is 4 times lower than the bridged circuit and may not be enough to ensure a good voice volume.
- Make sure that the earphone traces in the PCB don't cross or run parallel to noisy traces (especially the power line)
- The cable to the speaker shall be a twisted pair with both the lines floating for the bridged output type, shielded with the shield to ground for the single ended output type.

### 8.2.1 Noise Filtering

The I/O of the PCB should have a noise filter close to the connector, to filter the high frequency GSM noise. The filter can be a  $\Pi$  of 2 capacitor and a inductance, with the one capacitor of 39pF - 0603 case , and the other capacitor of 1nF - 0603; the inductance shall have a value of 39 $\mu$ H .

## 8.3 Handset earphone design

As seen previously, a 16 Ohm speaker can be directly connected to the output pins EAR\_MT+ and EAR\_MT- of the TRIZIUM-GPS.

This solution is often the more cost effective, reducing the components count to a minimum. There are several limitations to the use of this solution: speaker direct connect imposes the speaker characteristics to be almost exactly the suggested ones, otherwise the power output may be reduced (if speaker impedance is bigger than 16Ohm) or the TRIZIUM-GPS ear port may be damaged (if speaker impedance is less than 15 Ohm).

The other limitation of the speaker direct connection is the power output capability of the TRIZIUM-GPS which is limited and for some particular applications may not be enough.

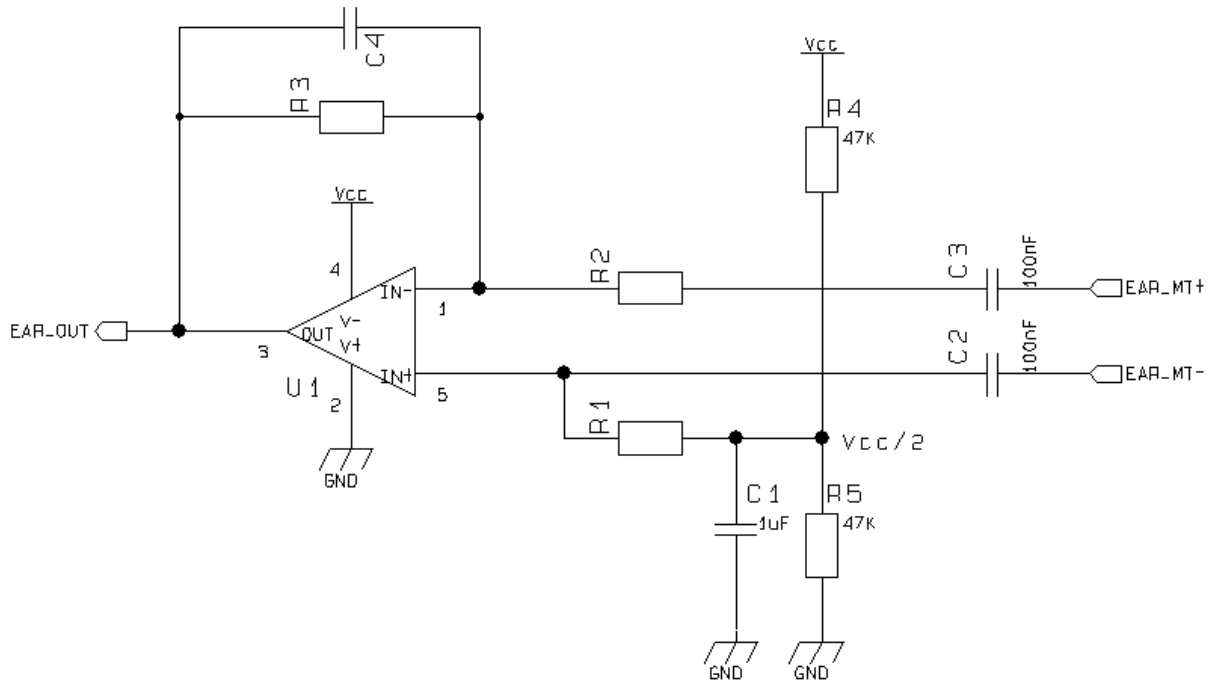

For these reasons, when the power output of the TRIZIUM-GPS is not enough or if the speaker characteristics are different from the suggested, then it is preferable to use an amplifier to increase the power and current output capabilities.

Again the output from the TRIZIUM-GPS is bridged and both lines should be used, where possible, as inputs to the power amplifier. This ensures a higher common mode rejection ratio, reducing the GSM current busts noise on the speaker output.

In this case the EAR\_MT lines from the TRIZIUM-GPS should be AC coupled with a capacitor of 100nF.

It is always desirable to have a mute control on the amplifier, in order to turn it off while the device is not sending signal to the output, in this manner the amplifier background noise which may be audible during idle conditions is cut off.

A principle schematic may be:

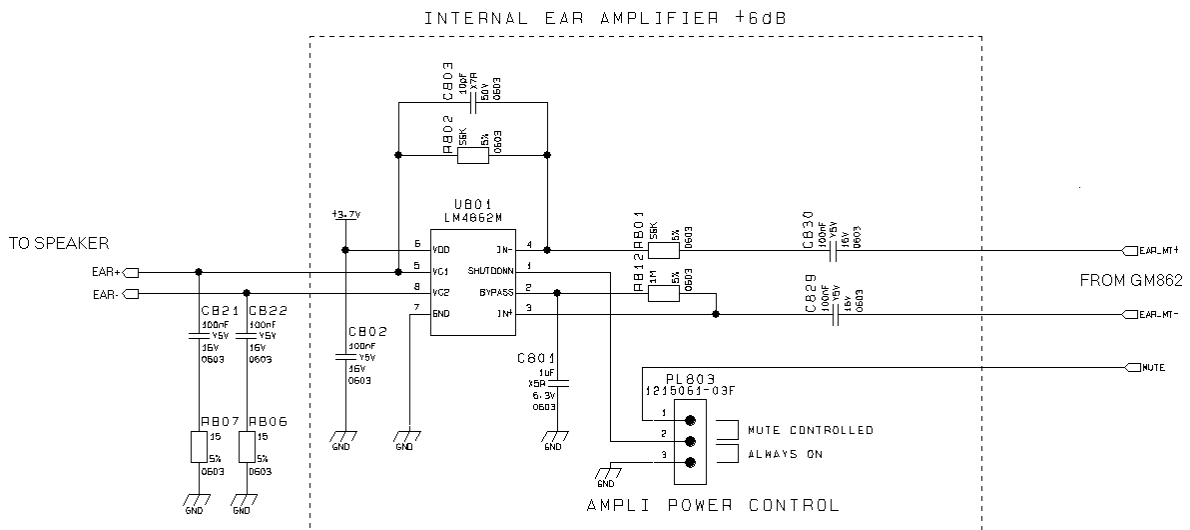

The resulting gain and high pass cut can be obtained with the formula:

$$Gain = \frac{R3}{R2}$$

$$freq. = \frac{1}{2\pi * R3 * C4} [Hz]$$

And an example of internal Ear amplifier is:

Some amplifier require a low impedance load at high frequency in order to avoid auto oscillation, this can be made with a capacitor (100nF) in series with a resistor (15 Ohm).

When designing your application, remember to provide an adequate bypass capacitor to the amplifier and place it close to the power input pin of the IC, keeping the traces as short as possible.

## 8.4 Hands Free earphone (low power) design

The same design considerations made for the handset are valid for the hands free earphone, the only difference is that the external ear audio output level from the TRIZIUM-GPS is 6dB lower than the internal one, so the gain of the amplifier must be 6dB higher to provide the same audio level.

## 8.5 Car Kit speakerphone design

For the car kit speaker phone function the power output requirement is usually at least 4W, therefore an amplifier is needed to boost the TRIZIUM-GPS output.

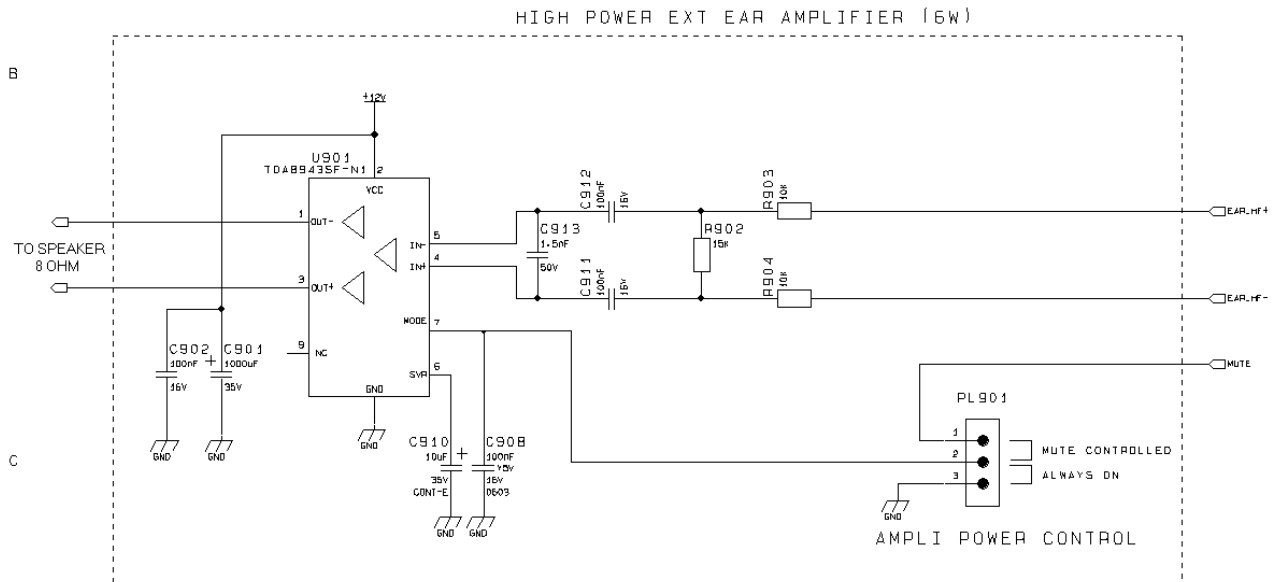

The design of the amplifier shall comply with the following guidelines:

- The input to the amplifier **MUST** be taken from the external audio path (EAR\_HF+, EAR\_HF-) of the TRIZIUM-GPS, because of its echo canceller parameters suited to a car cabin use.
- The amplifier shall have a gain of 30-40 times ( 29-32 dB) to provide the desired output power of 5-10W with the signal from the TRIZIUM-GPS external audio output lines (EAR\_HF).
- If the amplifier has a fixed gain then it can be adjusted to the desired value by reducing the input signal with a resistor divider network.
- The amplifier shall have a mute control to be used while not in conversation. This results in two benefits: eliminating the background noise when not in conversation and saving power.
- The power to the amplifier should be decoupled as much as possible from the TRIZIUM-GPS power supply, by either keeping separate wires and placing bypass capacitors of adequate value close to the amplifier power input pins.
- The biasing voltage of the amplifier shall be stabilised with a low ESR (e.g. a tantalum) capacitor of adequate value.

***NOTE: The TRIZIUM audio path connected to the car kit hands free amplifier MUST be the external one (EAR\_HF), otherwise the echo cancellation will not be done due to the difference in the echo canceller characteristics of the TRIZIUM internal audio path from the external audio path.***

An example of car kit amplifier schematic can be:

## 9 General Purpose I/O

The general purpose I/O pins can be configured to act in three different ways:

- input
- output
- alternate function (internally controlled)

Input pins can only be read and report the digital value (high or low) present on the pin at the read time; output pins can only be written or queried and set the value of the pin output; an alternate function pin is internally controlled by the TRIZIUM-GPS firmware and acts depending on the function implemented.

Not all GPIO pins support all these three modes:

- GPIO6 supports all three modes and can be input, output, alarm output (Alternate function)
- GPIO7 supports all three modes and can be input, output, buzzer output (Alternate function)

All GPIO pins are 2.8V CMOS signals and their interface levels are the same specified in the paragraph **Serial Port**.

### 9.1 Using a GPIO pin as INPUT

The GPIO pins, when used as inputs, can be connected to a digital output of another device and report its status, provided this device has interface levels compatible with the 2.8V CMOS levels of the GPIO.

If the digital output of the device to be connected with the GPIO input pin has interface levels different from the 2.8V CMOS, then it can be connected to GPIO1 or can be buffered with an open collector transistor, provided a 47K Ohm pull-up resistor is connected as seen in the paragraph 6.2 5V UART level translation.

### 9.2 Using a GPIO pin as OUTPUT

The GPIO pins, when used as outputs, can drive 2.8V CMOS digital devices or compatible hardware. When set as outputs, the pins have a push-pull output and therefore the pull-up resistor may be omitted.

## 9.3 Using the Alarm Output GPIO6

The GPIO6 pin, when configured as Alarm Output, is controlled by the TRIZIUM-GPS module and will rise when the alarm starts and fall after the issue of a dedicated AT command.

This output can be used to power up the TRIZIUM controlling microcontroller or application at the alarm time, giving you the possibility to program a timely system wake-up to achieve some periodic actions and completely turn off either the application and the TRIZIUM-GPS during sleep periods, dramatically reducing the sleep consumption to few  $\mu\text{A}$ .

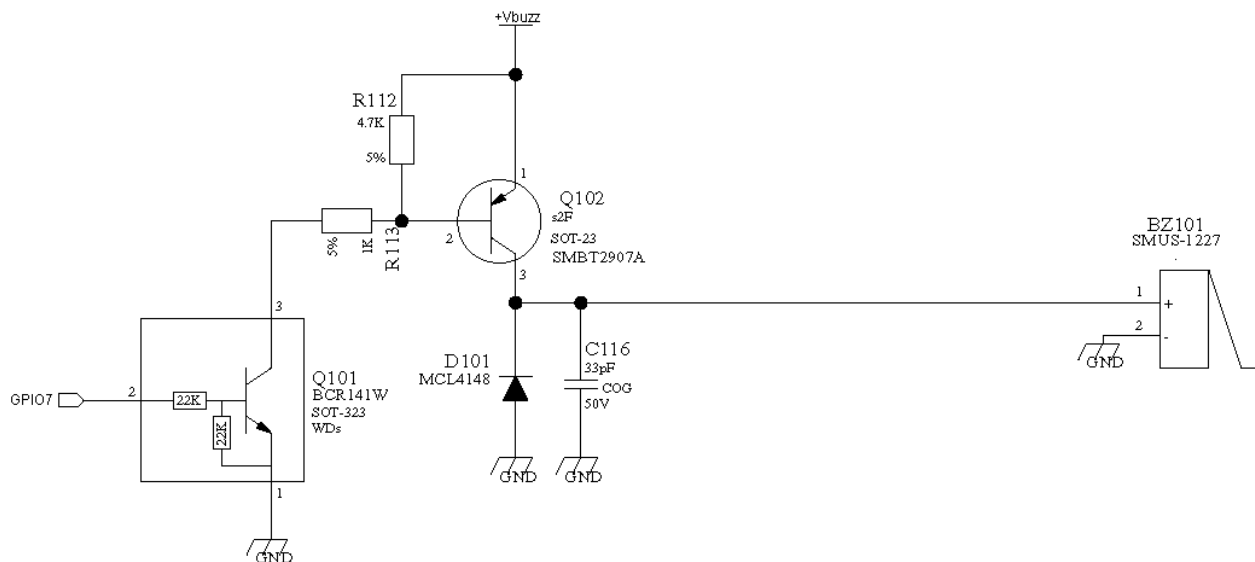

In battery powered devices this feature will greatly improve the autonomy of the device.

## 9.4 Using the Buzzer Output GPIO7

The GPIO7 pin, when configured as Buzzer Output, is controlled by the TRIZIUM-GPS module and will drive with appropriate square waves a Buzzer driver.

This permits to your application to easily implement Buzzer feature with ringing tones or melody played at the call incoming, tone playing on SMS incoming or simply playing a tone or melody when needed by your application.

A sample interface scheme is included below to give you an idea of how to interface a Buzzer to the GPIO7:

**NOTE:** To correctly drive a buzzer a driver must be provided, its characteristics depend on the Buzzer and for them refer to your buzzer vendor.

# 10 Interface connector Pinout

Pin n°	Signal	I/O	Function	Type
1-3	VBATT	-	Main power supply	Power
4-6	GND	-	Ground	Power
7	GPSA_OUT_GPS	O	Reserved	-
8	GPIO_CE1_GPS		Reserved	CMOS 2.8V
9	GPIO_CE2_GPS		Reserved	CMOS 2.8V
10	GPIO_GC_GPS		Reserved	CMOS 2.8V
11	CHARGE	AI	Charger input	Power
12	ON/OFF	I	Input command for switching power ON or OFF (toggle command). The pulse to be sent to the TRIZIUM must be equal or greater than 1 second.	Pull up to VBATT
13	*RESET	I	Reset input	-
14	VOUT	O	Power output for external accessories	-
15	VRTC	AO	VRTC Backup capacitor	Power
16	AXE	I	Handsfree switching	CMOS 2.8V
17	MIC_HF-	AI	Handsfree microphone input; phase -, nominal level 3mVrms	Audio
18	MIC_HF+	AI	Handsfree microphone input; phase +, nominal level 3mVrms	Audio
19	MIC_MT-	AI	Handset microphone signal input; phase-, nominal level 50mVrms	Audio
20	MIC_MT+	AI	Handset microphone signal input; phase+, nominal level 50mVrms	Audio
21	EAR_HF-	AO	Handsfree ear output, phase -	Audio
22	EAR_HF+	AO	Handsfree ear output, phase +	Audio
23	EAR_MT+	AO	Handset earphone signal output, phase +	Audio
24	EAR_MT-	AO	Handset earphone signal output, phase -	Audio
25	VSIM	AO	External SIM signal – Power	3V ONLY
26	CCIO	I/O	External SIM signal - Data I/O	3V ONLY

Pin n°	Signal	I/O	Function	Type
27	CCRST	O	External SIM signal – Reset	3V ONLY
28	CCLK	O	External SIM signal – Clock	3V ONLY
29	CCIN	I	External SIM signal - Presence (active low)	CMOS 2.8V
30	TX_TRACE	O	TX Data for debug monitor	CMOS 2.8V
31	RX_TRACE	I	RX Data for debug monitor	CMOS 2.8V
32	GPIO4	I/O	Configurable general purpose I/O	CMOS 2.8V
33	GPIO2	I/O	Configurable general purpose I/O	CMOS 2.8V
34	TX_PROG	O	Serial data output to DTE	CMOS 2.8V
35	RX_PROG	I	Serial data input from DTE	CMOS 2.8V
36	CTS	O	Output for Clear to send signal (CTS) to DTE	CMOS 2.8V
37	RING	O	Output for Ring indicator signal (RI) to DTE	CMOS 2.8V
38	DSR	O	Output for Data set ready signal (DSR) to DTE	CMOS 2.8V
39	DCD	O	Output for Data carrier detect signal (DCD) to DTE	CMOS 2.8V
40	DTR	I	Input for Data terminal ready signal (DTR) from DTE	CMOS 2.8V
41	RTS	I	Input for Request to send signal (RTS) from DTE	CMOS 2.8V
42	ADC_IN	AI	Analog/Digital converter input	A/D
43	GPIO1	I/O	General Purpose I/O (could be used to switch on the GPS module in Internal-Mode)	CMOS 2.8V
44	STAT_LED	O	TRIZIUM Status indicator led	CMOS 2.8V
45	GPIO5	I/O	General Purpose I/O	CMOS 2.8V
46	GPIO7	I/O	General Purpose I/O	CMOS 2.8V
47	TM	I/O	RESERVED	CMOS 2.8V
48	MON1	I/O	RESERVED	CMOS 2.8V
49	GPIO8	I/O	General Purpose I/O	CMOS 2.8V
50	GPIO9	I/O	General Purpose I/O	CMOS 2.8V
51	GPIO10	I/O	General Purpose I/O	CMOS 2.8V
52	GPIO11	I/O	General Purpose I/O	CMOS 2.8V

Pin n°	Signal	I/O	Function	Type
53	GPIO12	I/O	General Purpose I/O	CMOS 2.8V
54	GPIO13	I/O	General Purpose I/O	CMOS 2.8V
55	GPIO3	I/O	General Purpose I/O	CMOS 2.8V
56	GPIO6	I/O	General Purpose I/O	CMOS 2.8V
57	TX2_GPS	O	GPS UART 2 GPS commands	CMOS 2.8V
58	RX2_GPS	I	GPS UART 2 GPS commands	CMOS 2.8V
59	TX0_GPS	O	GPS UART 0 NMEA output	CMOS 2.8V
60	RX0_GPS	I	GPS UART 0 , high	CMOS 2.8V
61	VCC_EN_GPS	I	Enable GPS supply (Enable High)	-
62	ANTSTAT_GPS	O	Antenna Ext Status	-
63	PPS	-	Reserved	-
64	TEST0	-	Reserved	-
65	ENABLE	-	Reserved	-
66	GS	-	Reserved	-
67	TEST1	-	Reserved	-
68	LOCK	-	Reserved	-
69	*RST	I	GPS Reset input	-
70	VGPS	I	GPS Power supply	Power
71	CLK	O	RESERVED	CMOS 2.8V
72	MRST	I	RESERVED	CMOS 2.8V
73	MTSR	O	RESERVED	CMOS 2.8V
74	TP108	-	Reserved	-
75	TP109	-	Reserved	-
76	TP110	-	Reserved	-
77	TP111	-	Reserved	-
78	TP112	-	Reserved	-
79	TP113	-	Reserved	-
80	TP114	-	Reserved	-

## 11 Interface connectors

### 11.1 Board to Board Connector (SO108)

The interface connector is provided by FCI ([www.fciconnect.com](http://www.fciconnect.com))

Product Family : BERGSTACK

Type: Board to Board plug connector

Pitch: 0.8mm

Contacts : 2x40ct

Part N° : 61083-08300

## 12 RF connector (SO104 and SO105)

The Telit TRIZIUM-GPS Transceiver module includes two 50 Ohm MMCX coaxial female 2 pin Angle Coax SMD J01341A0081 connectors to allow the GSM RF antenna and the GPS antenna connection:

**GSM and GPS Antenna coax connectors**

## 13 Document Change Log

<b>Revision</b>	<b>Date</b>	<b>Changes</b>
ISSUE #1	23/05/05	First release
ISSUE #2	07/07/05	added 3.3.1 Stat led
ISSUE #3	19/07/05	Added table with supply voltage limits
